

Google Ads API — Tool Design Document

Naviio, Inc. · naviio.com · Prepared for Google Ads API Basic Access review · June 2026

1. Product overview

Naviio is a financial intelligence platform for small and medium businesses (SMBs). It connects to a customer's financial data sources (bank accounts via Plaid, payments via Stripe, accounting via QuickBooks/Xero) and presents a live, reconciled view of their finances: P&L, cash flow, budgets, and forecasts.

The Google Ads API powers one feature: **advertising spend validation**. SMB owners see charges such as "GOOGLE *ADS7644-1234" on their bank statement with no visibility into what the money bought. With the customer's OAuth consent, Naviio reads their Google Ads daily performance reports and reconciles each bank charge against the exact billing window it covers, displaying the associated metrics (impressions, clicks, conversions, cost) next to the transaction.

2. Tool type and scope

Reporting-only. The tool performs exclusively read-only reporting queries. It does not create, edit, pause, or remove campaigns, ad groups, ads, keywords, budgets, or bids, and performs no mutate operations of any kind. As a reporting-only tool, Required Minimum Functionality (RMF) for campaign management does not apply.

3. Users and access model

Naviio's customers (external SMB users) connect their own Google Ads accounts through a standard OAuth 2.0 authorization flow inside the Naviio web application. Each customer authorizes access only to their own account(s); refresh tokens are stored encrypted (AES-256-GCM) and scoped to that customer's organization. Data retrieved for a customer is displayed only to that customer and is never shared with third parties or used for any purpose other than presenting their own reporting back to them. Disconnecting revokes the token and stops all syncing.

4. API usage detail

Endpoints used:

- `customers:listAccessibleCustomers` — enumerate the ad accounts the customer authorized
- `customers/{id}/googleAds:searchStream` — daily account-level reporting (GAQL)

The reporting query (executed once per connected account per day):

```
SELECT segments.date, metrics.cost_micros, metrics.impressions,
       metrics.clicks, metrics.conversions, metrics.conversions_value,
       customer.descriptive_name
FROM customer WHERE segments.date BETWEEN {start} AND {end}
```

On first connection the window covers the trailing 13 months (to support year-over-year analysis); routine daily syncs re-read the trailing 40 days so conversion restatements are absorbed. Results are stored as one row per (customer, ad account, day) in Naviio's database. Expected volume: one searchStream query per connected account per day, well under Basic Access limits.

5. Architecture and data flow

1. Customer clicks "Connect Google Ads" in Naviio → standard OAuth 2.0 consent (scope: adwords) → refresh token stored encrypted.
2. A scheduled background sync (daily) calls searchStream per authorized account and upserts daily metrics rows.
3. Naviio's matching engine reconciles each Google Ads bank charge (detected from the bank statement descriptor) against contiguous runs of platform-reported daily spend, identifying the billing window the charge covers.
4. In the customer's expense view, the matched transaction shows a verification line ("matches Google Ads billing May 3–17") and the window's metrics: impressions, clicks, CTR, CPC, conversions, cost per conversion.

6. User interface

The feature surface is a small popover attached to advertising transactions in the customer's expense table:

Transactions		
Jun 4	GOOGLE *ADS7644-1234 [Google Ads ♦]	Advertising
- \$1,247.83		
✓ Verified: matches Google Ads billing May 21 – Jun 2 (13 days)		
Impressions 412,304 · Clicks 8,940 · CTR 2.17% · CPC \$0.14 · Conversions 312 · Cost/conv \$4.00		

If no billing window reconciles exactly, the popover clearly labels the figures as trailing-30-day performance and states the difference between platform-reported spend and the bank charge — the tool never presents an approximate match as exact.

7. Data handling and security

OAuth tokens are encrypted at rest (AES-256-GCM) in PostgreSQL; monetary values are stored as exact decimals. All API access is scoped per customer organization; no cross-customer aggregation of Google Ads data is performed. Customers can disconnect at any time, which deletes the integration tokens and halts syncing. Naviio does not resell, share, or expose Google Ads data to any party other than the customer who owns the account.

8. Summary

Naviio uses the Google Ads API as a read-only reporting source so SMB owners can finally validate their advertising spend — reconciling real bank charges against platform-reported performance. Usage is low-volume (one reporting query per account per day), strictly scoped, and contains no campaign-management functionality.
